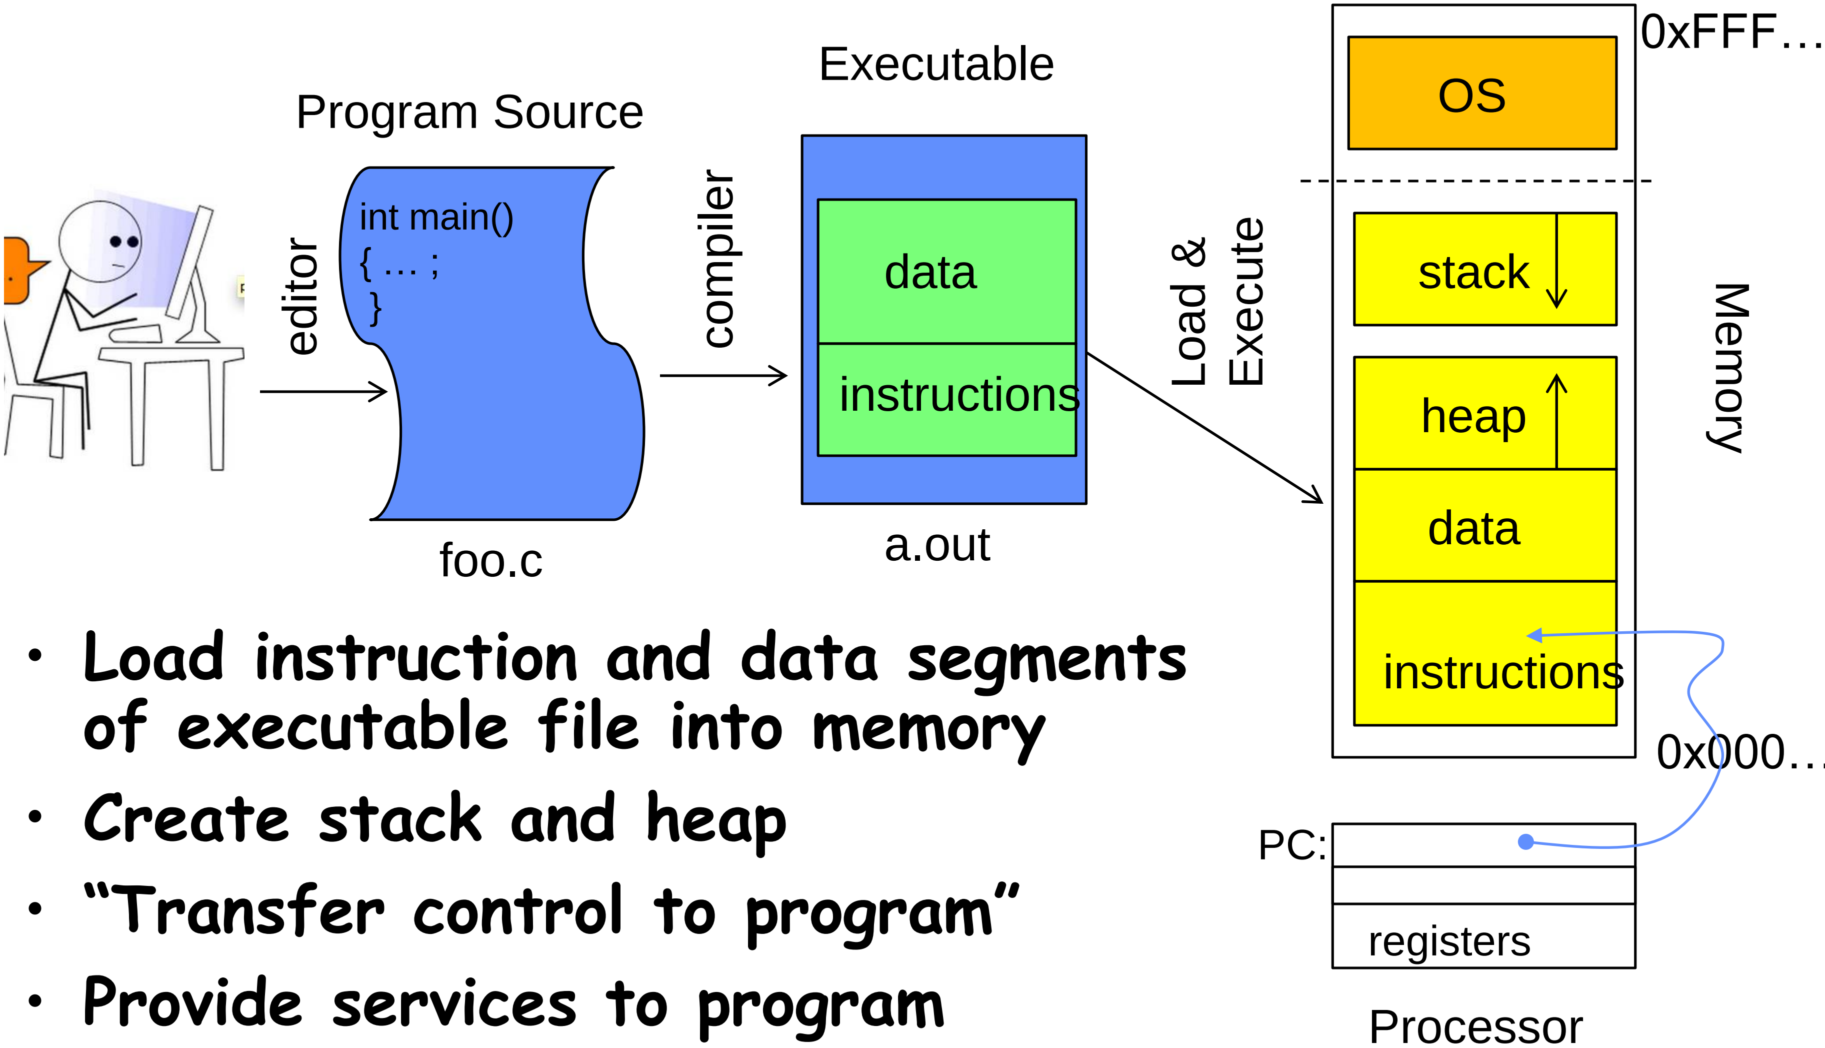
Operating Systems

Processes

Bheemarjuna Reddy Tamma
IIT HYD

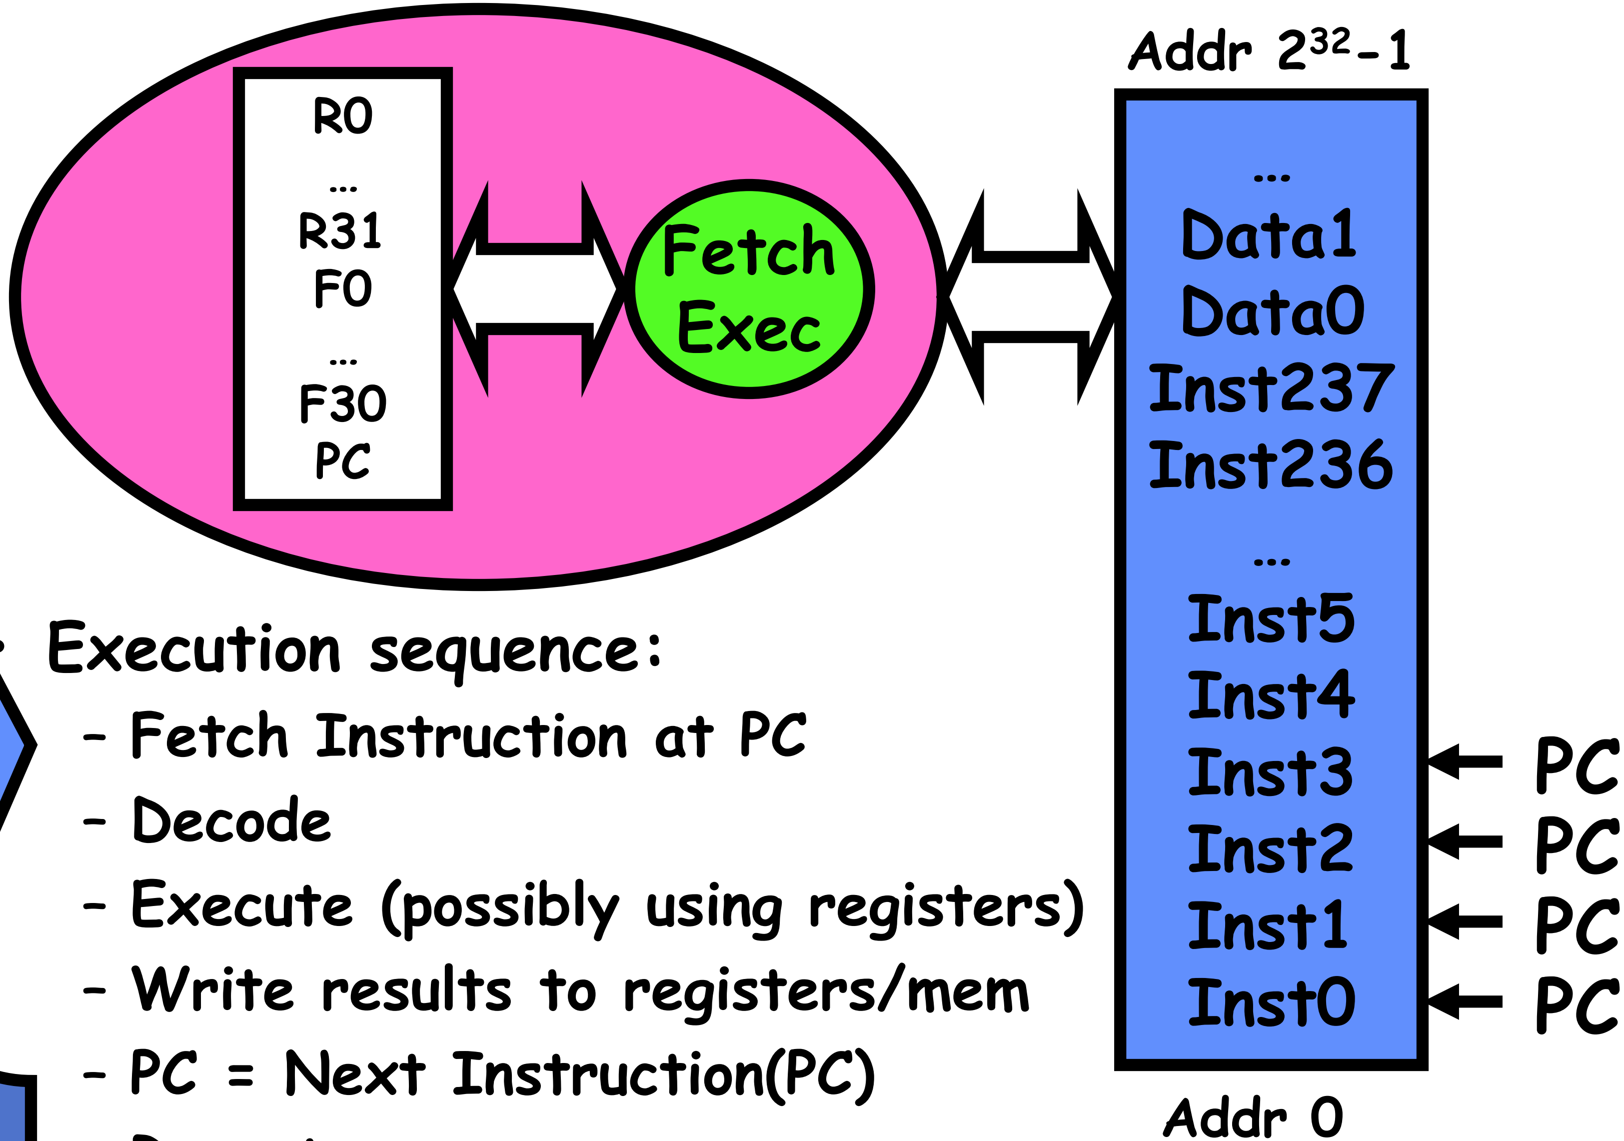
Note: Some slides and/or pictures in the following are adapted from slides ©2005 Silberschatz, Galvin, and Gagne. Many slides are from Prof John Kubi, UCB.

OS Bottom Line: Run Programs



- Load instruction and data segments of executable file into memory
- Create stack and heap
- "Transfer control to program"
- Provide services to program
- While protecting itself (OS) and program

What happens during execution?



- Execution sequence:
  - Fetch Instruction at PC
  - Decode
  - Execute (possibly using registers)
  - Write results to registers/mem
  - PC = Next Instruction(PC)
  - Repeat

Thread of Control

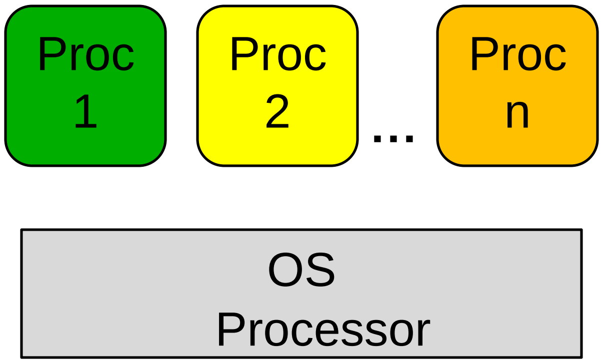
- Thread: Single unique execution context
  - Independent Fetch/Decode/Execute loop
  - Operating in some Address space
  - Program Counter, Registers, Execution Flags, Stack
- Certain registers hold the *context* of thread
  - PC register holds the address of executing instruction in the thread
  - Stack pointer holds the address of the top of stack
  - May be defined by the instruction set architecture or by compiler conventions
- A thread is executing on a processor when it is resident in the processor registers
  - Registers hold the root state of the thread
    - » The rest is "in memory"

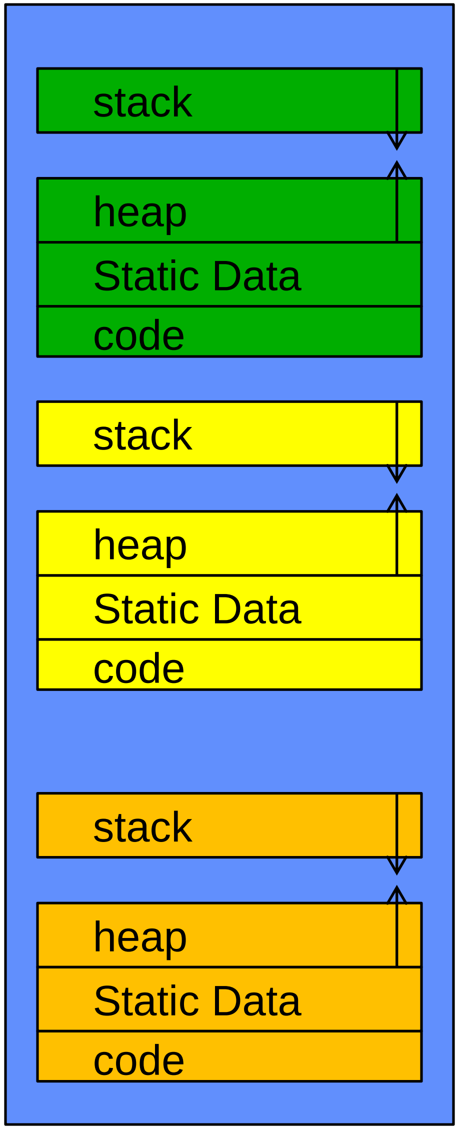
Concurrency vs Parallelism

- Uniprogramming: *one thread at a time in the system*
  - MS/DOS, early Macintosh, Batch processing
  - Easier for operating system builder
  - Does this make sense for personal computers?
- Multiprogramming: *more than one thread at a time in the system*
  - Multics, UNIX/Linux, OS/2, Windows 10, Mac OS X
  - Often called "multitasking", but multitasking (aka time sharing and concurrency) is bit different from it
    - » CPU executes multiple jobs alternatively by switching from one to other, but switching is so frequent to provide interactive computing (time slice)
- Multi-processor (or ManyCore) System $\Rightarrow$ Multiprogramming or Multitasking?
  - No, it's parallel programming!

https://techdifferences.com/difference-between-concurrency-and-parallelism.html

Multiprogramming/Concurrency-Multiple Threads of Control

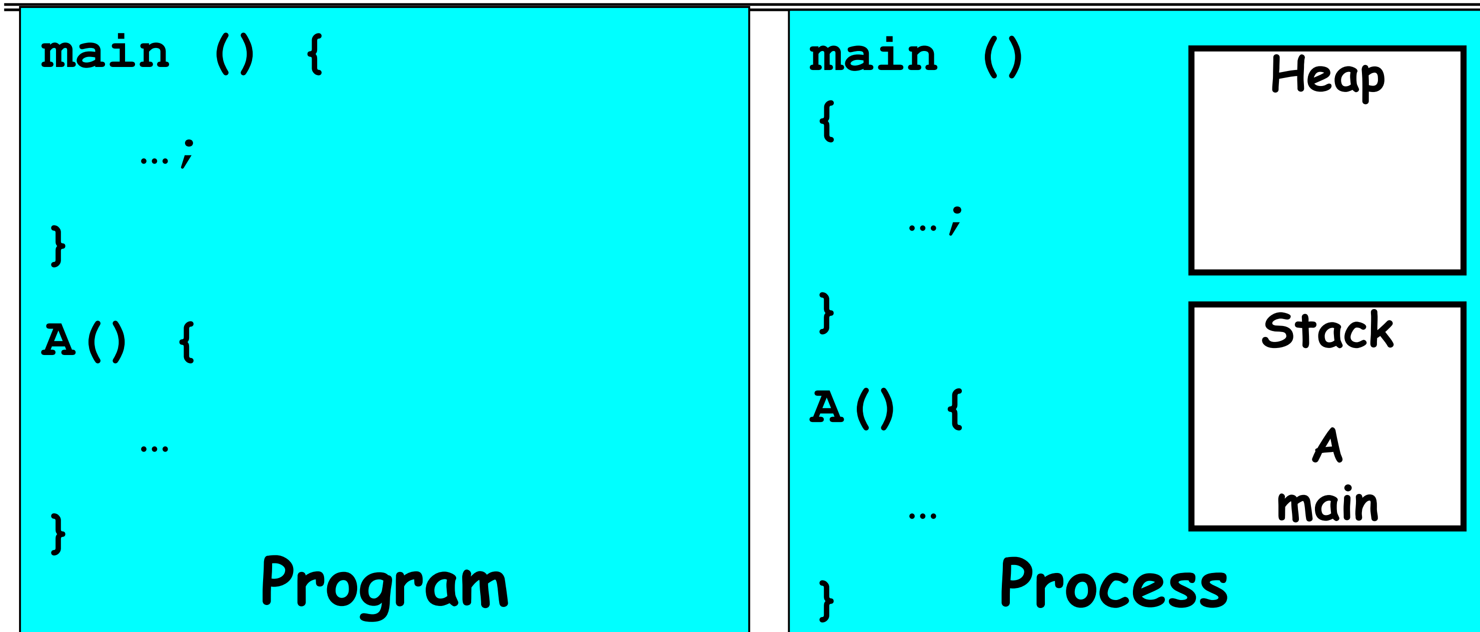




Traditional UNIX Process

- Process: *Operating system abstraction to represent what is needed to run a single program*
  - Process is an instance of a program in execution
  - Often called a "HeavyWeight Process"
  - There is no concurrency in a heavyweight process → a single thread!
  - Collection of data structures to fully describes how far the execution of the program has progressed
  - Formally: a single, sequential stream of execution in its *own* address space
- Process has two parts:
  1. Sequential Program Execution Stream
     - » Code executed as a *single, sequential* stream of execution
     - » Includes State of CPU registers
  2. Protected Resources:
     - » Main Memory State (contents of Address Space)
     - » I/O state (i.e. file descriptors)

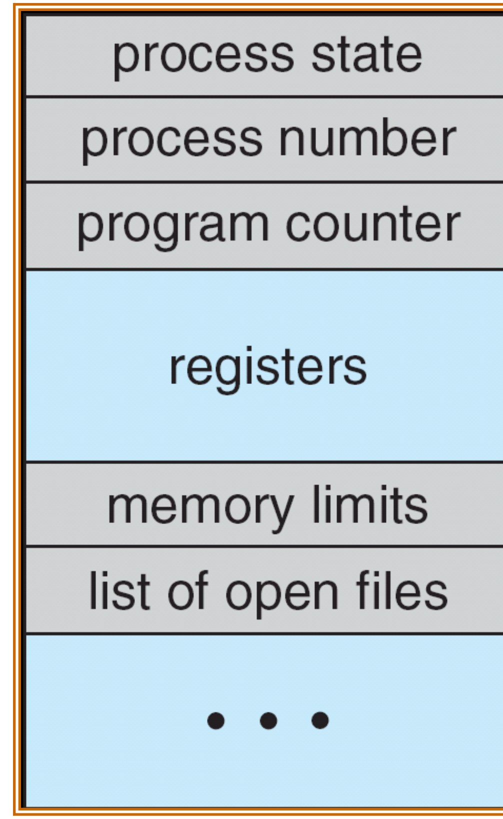
Process = Program ??



- Program is passive entity, but process is active entity
  - Program becomes process when its executable file is loaded into memory → click on icon or type it on command line (shell)
- More to a process than just a program:
  - Program is just a part of the process state
  - I run vi editor on lectures.txt, you run it on homework.c – Same program, but different processes
- Less to a process than a program:
  - A program can invoke more than one process
  - cc starts up cpp, cc1, cc2, as, and ld

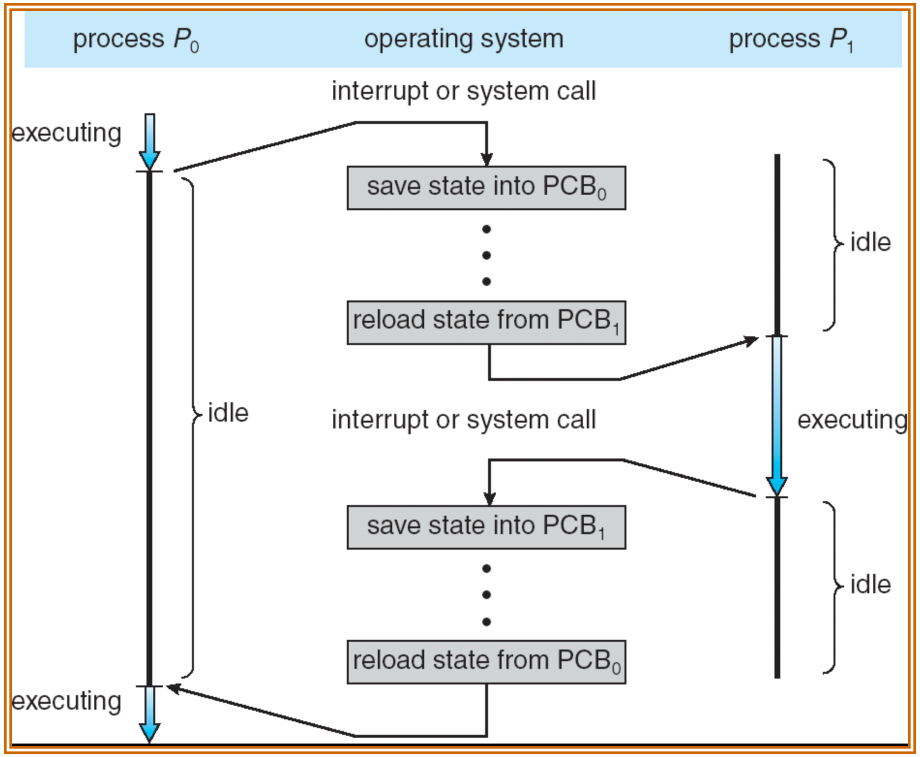
How do we multiplex processes?

- The current state of process held in a DS called process control block (PCB):
  - This is a "snapshot" of the execution and protection environment
  - Only one PCB active at a time
- Give out CPU time slice to different processes (Scheduling):
  - Only one process "running" at a time
  - Give more time to important processes e.g, I/O, foreground jobs
- Give pieces of resources to different processes (Protection):
  - Controlled access to non-CPU resources
  - Sample mechanisms:
    - » Memory Mapping: Give each process its own (virtual) address space
    - » Kernel/User duality: Arbitrary multiplexing of I/O through system calls



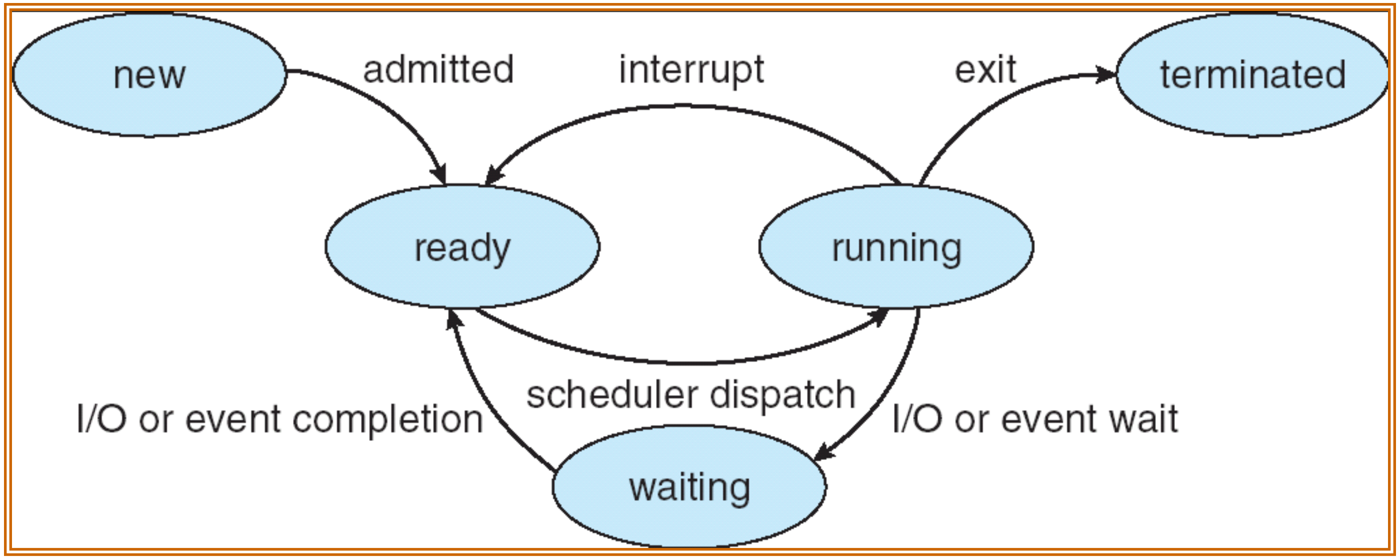
Process Control Block (PCB)

CPU Switch From Process to Process



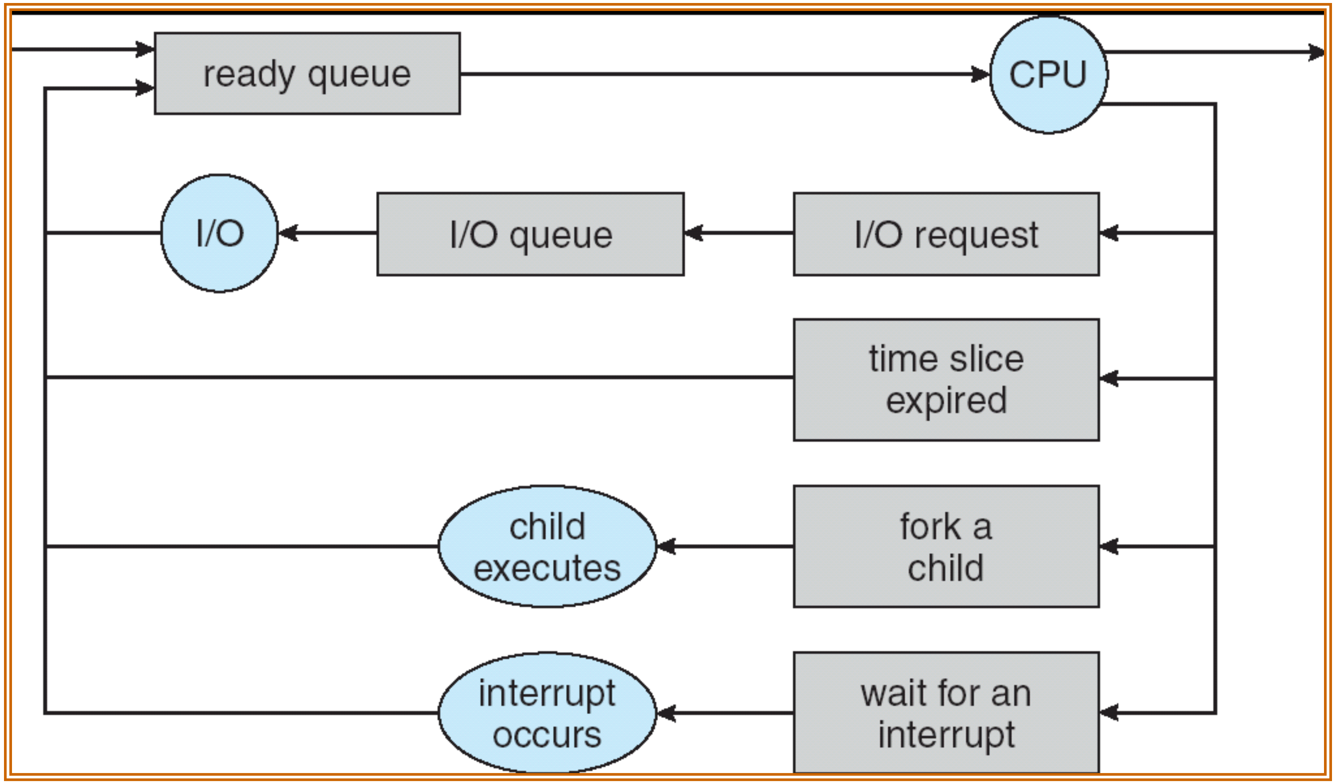
- **This is also called a "context switch"**
- **Code executed in kernel above is overhead as the system does no useful work while switching**
  - **Overhead (~ microsecs) sets minimum practical switching time**
  - **The more complex OS and PCB ➔ the longer context switch time**
  - **Some hardware provides multiple sets of registers ➔ multiple contexts loaded at once → no saving/reloading overhead**

Diagram of Process State



- As a process executes, it changes its *state*
  - new: The process is being created
  - ready: The process is waiting to run by CPU
  - running: Instructions are being executed by CPU
  - waiting: Process waiting for some event to occur
  - terminated: The process has finished execution

Process Scheduling (Queue representation)

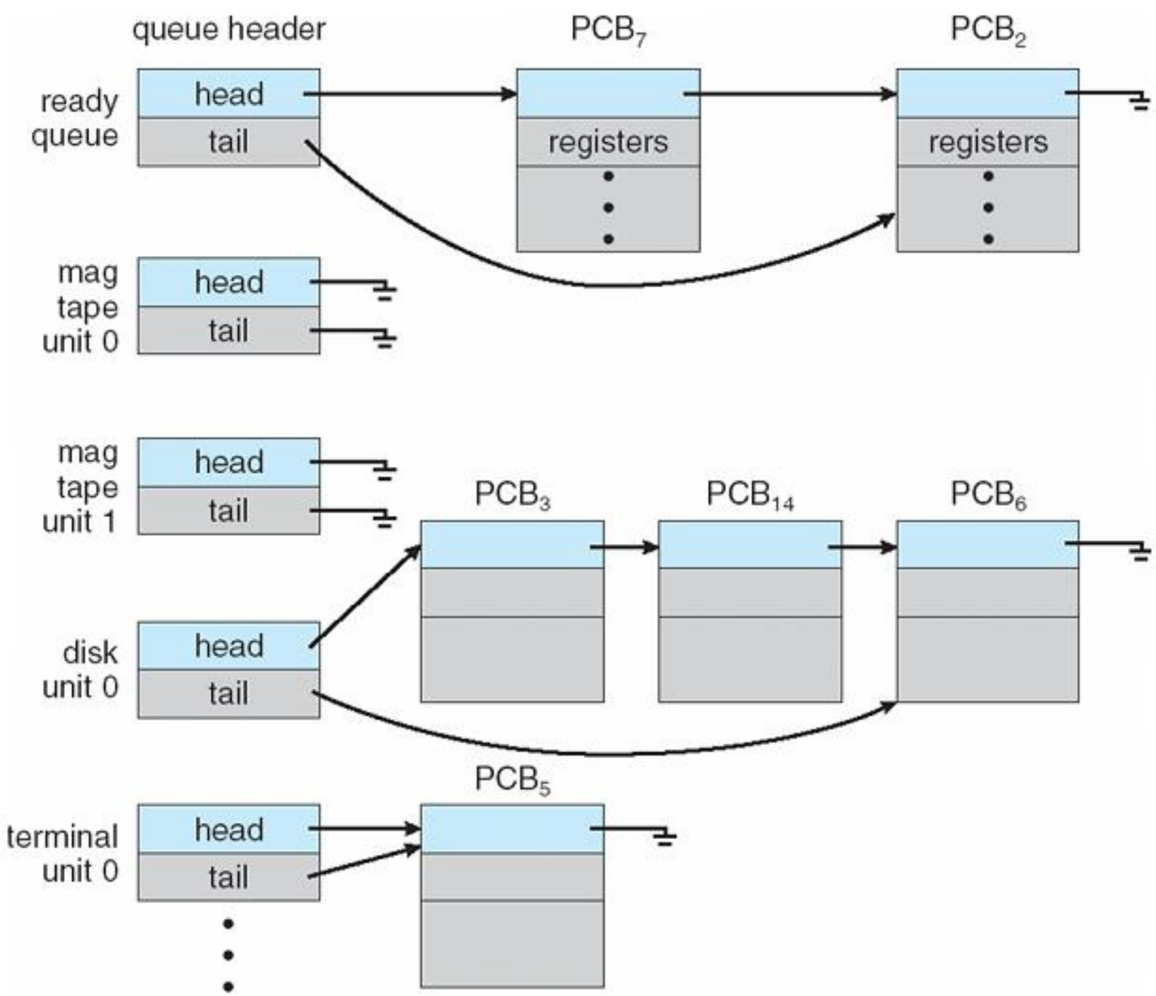


- PCBs move from queue to queue as they change state
  - Decisions about which order to remove from queues are Scheduling decisions
  - Many algorithms possible for queues of CPU ands I/O devices (discussed later)

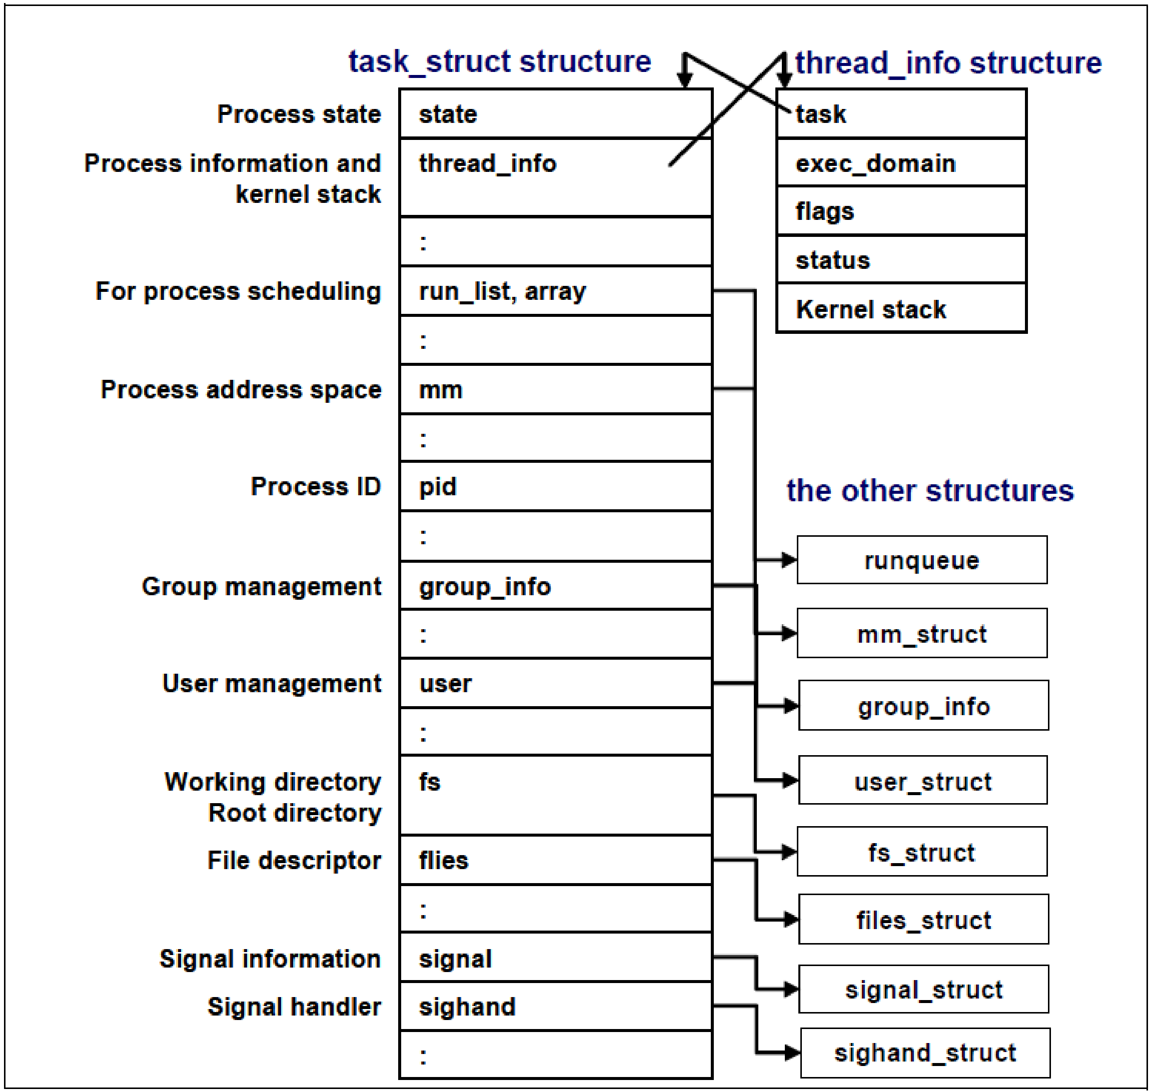
CPU Scheduler

```
if ( readyProcesses(PCBs) ) {
        nextPCB = selectProcess(PCBs);
        run( nextPCB );
} else {
        run_idle_process();
}
```

Ready Queue and I/O Device Queues



Linux Task Struct



Linux Task Struct (also called Process Descriptor):

https://github.com/torvalds/linux/blob/master/include/linux/sched.h

https://github.com/hungys/tech-note/blob/master/linux_kernel/process.md

What does it take to create a process?

- Must construct new PCB
  - Inexpensive
- Must set up new page table for address space
  - More expensive (discussed later)
- Copy data from parent process? (Unix `fork()`)
  - Semantics of Unix `fork()` are that the child process gets a complete copy of the parent memory and I/O state
  - Originally *very* expensive
  - Much less expensive with “copy-on-write”
- Copy I/O state (file handles, etc)
  - Medium expense

How to create a process?

- Double click on an icon or type program name on command-line (shell)
- After boot, OS starts the first process
  - E.g. sched for Solaris, ntoskrnel.exe for Windows
- The first process creates other processes:
  - the creator is called the parent process
  - the created is called the child process
  - parent/child relationships is expressed by a process tree
- Eg, in UNIX the second process is called *init*
  - it creates all the gettys (login processes) and daemons
  - it should never die
  - it controls the system configuration (#processes, priorities…)
- Explorer.exe in Windows for graphical interface

Processes Under UNIX

- Fork() system call is only way to create a new process
- int fork() does many things at once:
  - creates a new address space (for the child)
  - copies the parent's address space into the child's
  - starts a new thread of control in the child's address space
  - parent and child are equivalent -- almost
    - » in parent, fork() returns a non-zero integer
    - » in child, fork() returns a zero.
    - » difference allows parent and child to distinguish
- int fork() returns TWICE!

ProcEx1.c: Program using fork()

```
#include <sys/types.h>
#include <stdio.h>
#include <unistd.h>

int main()
{
pid_t pid;

    /* fork a child process */
    pid = fork();

    if (pid < 0) { /* error occurred */
       fprintf(stderr, "Fork Failed");
       return 1;
    }
    else if (pid == 0) { /* child process */
       execlp("/bin/ls","ls",NULL);
    }
    else { /* parent process */
       /* parent will wait for the child to complete */
       wait(NULL);
       printf("Child Complete");
    }

    return 0;
}
```

ProcEx2.c

```
#include <stdio.h>
#include <sys/types.h>  /* Primitive System Data Types */

int main(int argc, char **argv)
{
   char *myName = argv[0];
   int cpid = fork();
   if (cpid == 0) { //Child
      sleep(5); //sleeps for 5 secs
      printf("My pid: %d I am a child of %s My parent
pid: %d\n", getpid(), myName, getppid());
      exit(0);
   } else { //Parent
      printf("My pid: %d My child's pid: %d\n",
getpid(),cpid);
      exit(0);
   }
}
```

What does this program print?

ProcEx3.c

```
#include <stdio.h>
#include <sys/types.h>  /* Primitive System Data Types */
#include <unistd.h>
#include <sys/wait.h>
int main(void)
{
  int i, pid, status;
  pid = getpid();
  fprintf(stdout, "parent pid = %d\n", pid);

  pid = fork();
  if (pid == 0) /* child process is always 0 */
  {
    for (i= 0; i < 10; ++i)
    {
      fprintf(stdout,"In child: Iteration: %d\n",i);
      sleep(0.1);
    }
    fprintf(stdout, "In child: child exiting\n");
  }
  else /* parent process is non-zero (child's pid) */
  {
    //sleep(2); //to force child to run first
    fprintf(stdout, "In Parent: child pid = %d\n", pid);
    fflush(stdout);
    fprintf(stdout, "In Parent: waiting for child\n");
    //wait(NULL); //wait for any child to change state
    //wait(&status); //status is stored here
    //waitpid(-1,&status,0); //wait for any child to change state
    waitpid(pid,&status,0); //wait for pid child to change state
    fprintf(stdout, "In Parent: Child exit status:%d\n",WEXITSTATUS(status));
    if(WIFEXITED(status))
      fprintf(stdout, "In Parent: Child exited normally\n");
    else if(WIFSIGNALED(status))
      fprintf(stdout, "In Parent: Child was killed by a signal!!\n");
    else
      fprintf(stdout, "In Parent: Child exited for other reasons\n");
    fprintf(stdout, "In Parent: child terminated\n");
    fprintf(stdout, "In Parent: parent exiting\n");
  }

  return 0;
}
```

Output of one of Runs: 1

```
parent pid = 26892
In Parent: child pid = 26893
In Parent: waiting for child
In child: Iteration: 0
In child: Iteration: 1
In child: Iteration: 2
In child: Iteration: 3
In child: Iteration: 4
In child: Iteration: 5
In child: Iteration: 6
In child: Iteration: 7
In child: Iteration: 8
In child: Iteration: 9
In child: child exiting
In Parent: Child exit status:0
In Parent: Child exited normally
In Parent: child terminated
In Parent: parent exiting
```

Output of one of Runs: 2

```
parent pid = 26898
In Parent: child pid = 26899
In child: Iteration: 0
In Parent: waiting for child
In child: Iteration: 1
In child: Iteration: 2
In child: Iteration: 3
In child: Iteration: 4
In child: Iteration: 5
In child: Iteration: 6
In child: Iteration: 7
In child: Iteration: 8
In child: Iteration: 9
In child: child exiting
In Parent: Child exit status:0
In Parent: Child exited normally
In Parent: child terminated
In Parent: parent exiting
```

ProcEx4.c

```
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>
#include <sys/wait.h>

int main(void)
{
fprintf(stdout,"Parent PID:%d\n",getpid());
fflush(stdout);

while(1) {
fork();
fprintf(stdout,"My PID:%d and My Parent
                                        PID:%d\n",getpid(),getppid());
}
return 0; }
```

ProcEx5.c

```
#include <stdio.h>
#include <sys/types.h>
#include <unistd.h>
#include <sys/wait.h>

int main(void)
{
fprintf(stdout,"Parent PID:%d\n",getpid());
fflush(stdout);

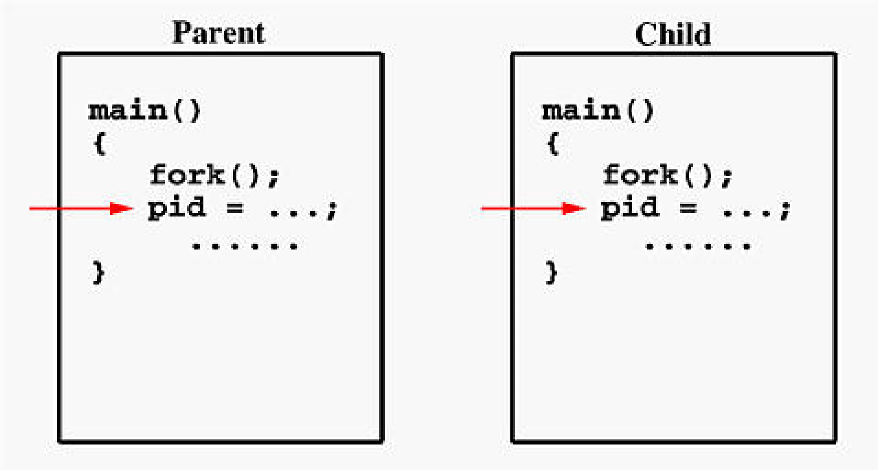
while(fork()) wait(NULL);
fprintf(stdout,"My PID:%d and My Parent
                                        PID:%d\n",getpid(),getppid());
return 0;
}
```

More Examples on fork( )

- http://www.csl.mtu.edu/cs4411.ck/www/NOTES/process/fork/create.html
- http://www.amparo.net/ce155/fork-ex.html
- http://home.adelphi.edu/sbloch/class/archive/271/fall2005/examples/c/fork_examples/
- http://man7.org/linux/man-pages/man2/vfork.2.html
  - Creates a child process and block parent till child finishes
  - Till finishes the child shares all memory with its parent, including the stack!

Fork is half the story

- Fork() gets us a new address space for child,
  - but parent and child share EVERYTHING
    - » memory, operating system state



- int exec(char *prgName) completes the picture
  - throws away the contents of the calling address space
  - replaces it with the program named by prgName
  - starts executing at header.startPC
  - exec does not return on successful load of new prog!
  - Returns -1 if it fails to load new prog
- Pros: Clean, simple; Con: duplicate operations

exec family

- execl("/bin/vi","vi","/home/user/ex1.txt",NULL); //PATH
- execlp("vi","vi","/home/user/ex1.txt",NULL); //File
- execle(path, arg1,…, envp[])
- execv(path, argv[]), execvp(progName, argv[])
- execvpe(progName, argv[], envp[])
- l: list of Args, v: vector of Args
- p: Searches folders listed in PATH environment variable
  - $echo $PATH or $env |grep PATH → /usr/bin:/usr/local/bin
- e: environment of progName to be specified
- The first argument should point to the PrgName associated with the file being executed.
- The list of arguments *must* be terminated by a null pointer
- execlp(), execvp(), and execvpe() duplicate actions of the shell in searching for an executable file if the specified PrgName does not contain / character
- Programs executed from the shell inherit all of the environment variables from the shell.

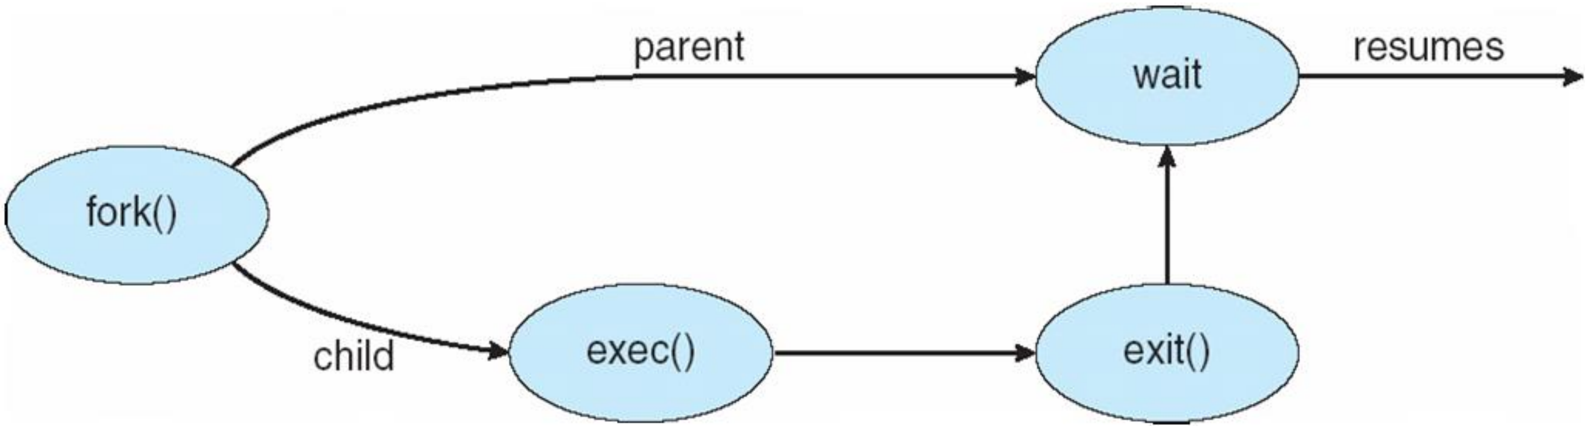
http://man7.org/linux/man-pages/man2/execve.2.html

https://www.gnu.org/software/libc/manual/html_node/Environment-Variables.html#Environment-Variables

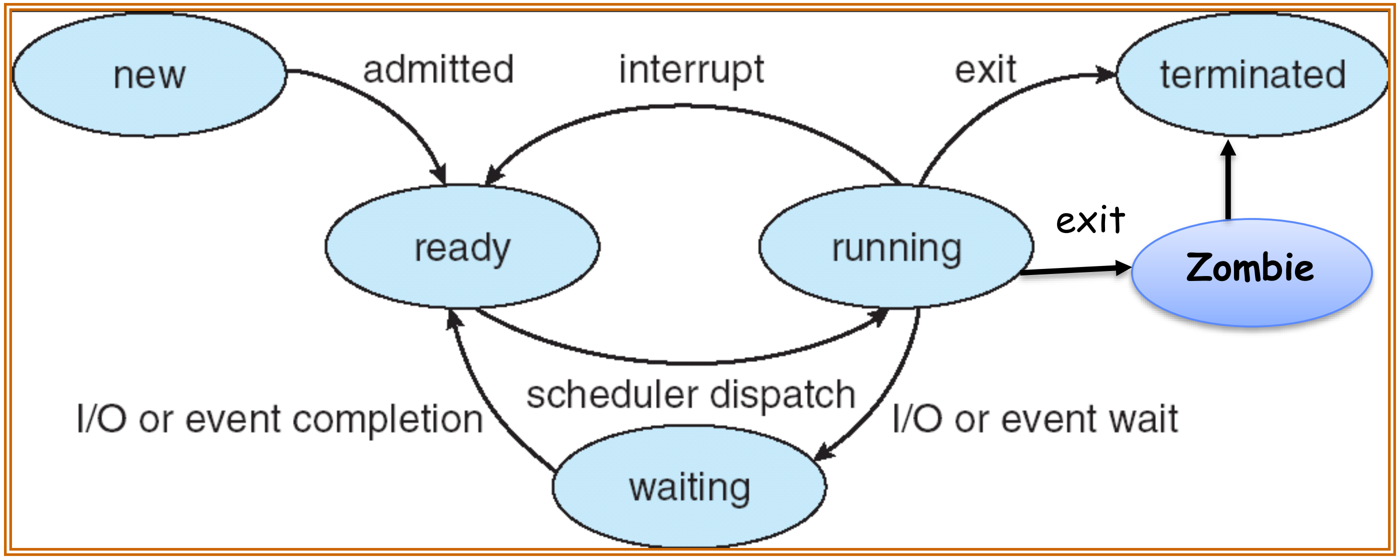
Process Termination

- Process executes last statement and OS decides(exit)
  - Output/return data from child to parent (via wait)
  - Process' resources are deallocated by operating system
- Child exits before parent calls up waitpid()
  - Child is in Zombie state and has entry still maintained in PCB linked list
  - It is removed later when parent calls waitpid( )
- Parent may terminate execution of child process (abort)
  - Child has exceeded allocated resources
  - Task assigned to child is no longer required
  - If parent is exiting first, child becomes orphan (it's not a state)
    - » Some OSes don't allow child to continue if parent terminates
      - All children terminated - *cascading termination*
      - *Linux: init daemon becomes parent of these orphan children;* upstart – init replacement daemon in Ubuntu; systemd – init replacement daemon designed to start processes in parallel → quick booting of OS

Process Life Cycle



Process State Diagram



Multiprocess Architecture – Chrome Browser

- Many web browsers ran as single process (some still do)
  - If one web site causes trouble, entire browser can hang or crash
- Google Chrome Browser is multiprocess with 3 different types of processes:
  - Browser process manages UI, disk and network I/O
  - Renderer process renders web pages, deals with HTML, Javascript. A new renderer created for each website opened on a tab
    - » Runs in sandbox restricting disk and network I/O, minimizing effect of security exploits
  - Plug-in process for each type of plug-in

Multitasking in Mobile Systems

- Some mobile systems (e.g., early version of iOS) allow only one process to run, others suspended
- Due to screen real estate & user interface limits, iOS provides for a
  - Single foreground process- controlled via user interface
  - Multiple background processes– in memory, running, but not on the display, and with limits
  - Limits include single, short task, receiving notification of events, specific long-running tasks like audio playback
- Android runs foreground and background, with fewer limits
  - Background process uses a service to perform tasks
  - Service can keep running even if background process is suspended
  - Service has no user interface, small memory use
